planet3D

Creates high-resolution renderings of the Earth and the major celestial bodies in our solar system for space mechanics applications.

Syntax

```
planet3D(planet,position,gmst,reference_plane,units,transparency)
```

NOTE: All parameters except for `planet` are optional. If you "skip over" parameters, you need to use empty bracket (i.e. "`[]`") as placeholders, otherwise you can emit parameters altogether. For example, if you don't want to specify `position`, but *do* want to specify `units`, then you would use the syntax `planet3D(planet,[],[],[],units)`. Alternatively, if we wanted to specify just the `position`, we could use the syntax `planet3D(planet,position)`.

NOTE: Use the `background` function (see Section) to set the plot background. When using `background` to set the plot background, the function call on `background` must occur *before* the function call on `planet3D`, otherwise the background will be plotted *over* the celestial body.

Description

`planet3D(planet,position,gmst,reference_plane,units,transparency)` draws a celestial body.

`planet`	`'Sun'`, `'Moon'`, `'Mercury'`, `'Venus'`, `'Earth'`, `'Earth Cloudy'`, `'Earth Night'`, `'Earth Night Cloudy'`, `'Mars'`, `'Jupiter'`, `'Saturn'`, `'Uranus'`, `'Neptune'`, or `'Pluto'`.
`position` *(optional)*	Specifies the position of the celestial body. If `position` is not specified, the function defaults to $(0, 0, 0)$. NOTE: If you are also specifying `units`, make sure you input `position` in the correct units (i.e. in the units you intend to use).
`gmst` *(optional)*	Specifies the Greenwich mean sidereal time (the angle from the direction of the vernal equinox to 0 degrees longitude, measured in degrees).
`reference_plane` *(optional)*	Specifies which reference plane the celestial body is drawn with respect to. If specified as `'equatorial'`, the reference plane is taken to be the equatorial plane of the celestial body. If specified as `'ecliptic'`, the celestial body will be tilted by the obliquity (i.e. the angle between the ecliptic plane and the equatorial plane).
`units` *(optional)*	Specifies the units the celestial body should be drawn in. Units available are `'km'`, `'AU'`, `'m'`, `'ft'`, `'mi'`, and `'nmi'`.
`transparency` *(optional)*	Specifies how transparent the celestial body is (0 for 100% transparency, 1 for 100% solid).

background

Sets the plot background for drawing celestial bodies in 3D.

Syntax

```
background(spec)
```

NOTE: The function call on `background` must occur before the function call on `planet3D`.

Description

`background(spec)` sets the plot background for drawing celestial bodies in 3D. `spec` refers to the specified background, and can be set to `'Black'`, `'Stars'`, or `'Milky Way'`.

****Table D-4, p. 1042*

Semi-Minor Axes

For MATLAB's `ellipsoid` function, we need the semi-minor axis, b, which can be calculated as

$$b = a(1 - f)$$

where a is the semi-major axis (assumed to be the equatorial radius) and f is the flattening [3, p. 7-4 (p. 73 in PDF)].

Saturn's Rings

Saturn's rings range from $7000\ \text{km}$ to $80000\ \text{km}$ from the surface of the planet [9].

Unit Conversions

Kilometers to Astronomical Units [13]:

$$1\ \text{AU} = 149597870\ \text{km} \quad \rightarrow \quad \boxed{1\ \text{km} = \frac{1}{149597870}\ \text{AU}}$$

Kilometers to Meters:

$$\boxed{1\ \text{km} = 1000\ \text{m}}$$

Kilometers to Feet:

$$1\text{ km} = \left(\frac{1000\text{ m}}{1\text{ km}}\right)\left(\frac{100\text{ cm}}{1\text{ m}}\right)\left(\frac{1\text{ in}}{2.54\text{ cm}}\right)\left(\frac{1\text{ ft}}{12\text{ in}}\right) \quad \rightarrow \quad \boxed{1\text{ km} = \frac{100000}{30.48}\text{ ft}}$$

Kilometers to Miles:

$$1\text{ km} = \left(\frac{100000/30.48\text{ ft}}{\text{km}}\right)\left(\frac{1\text{ mi}}{5280\text{ ft}}\right) \quad \rightarrow \quad \boxed{1\text{ km} = \frac{100000}{160934.4}\text{ mi}}$$

Kilometers to Nautical Miles:

$$1\text{ nmi} = 1852\text{ m} = 1.852\text{ km} \quad \rightarrow \quad \boxed{1\text{ km} = \frac{1}{1.852}\text{ nmi}}$$
